

Chair for Network Architectures and Services – Prof. Carle Department of Computer Science TU München

# Master Course Computer Networks IN2097

Prof. Dr.-Ing. Georg Carle Christian Grothoff, Ph.D.

Chair for Network Architectures and Services Institut für Informatik Technische Universität München http://www.net.in.tum.de

Principles of network applications

□ Web and HTTP

DNS

□ P2P applications

□ Summary

# Our goals:

- conceptual, implementation aspects of network application protocols
  - transport-layer service models
  - client-server paradigm
  - peer-to-peer paradigm
- learn about protocols by examining popular applicationlevel protocols
  - HTTP
  - DNS
- programming network applications
  - socket API

# Some network applications

- 🗆 e-mail
- □ web
- □ instant messaging
- □ remote login
- □ P2P file sharing
- multi-user network games
- □ streaming stored video clips
- □ voice over IP
- □ real-time video conferencing
- □ grid computing

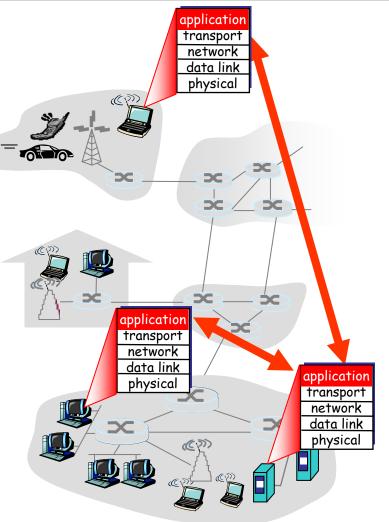

# **Creating a network application**

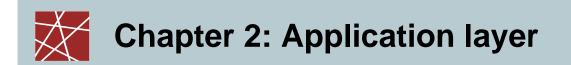

## write programs that

- run on (different) end systems
- communicate over network
- e.g., web server software communicates with browser software

## No need to write software for networkcore devices

- Network-core devices do not run user applications
- applications on end systems allows for rapid application development, propagation
- think whether a counter-example exists: what would be benefits if you could program your router?

# Principles of network applications

- □ Web and HTTP
- DNS
- □ P2P applications
- □ Summary

□ Client-server

□ Peer-to-peer (P2P)

□ Hybrid of client-server and P2P

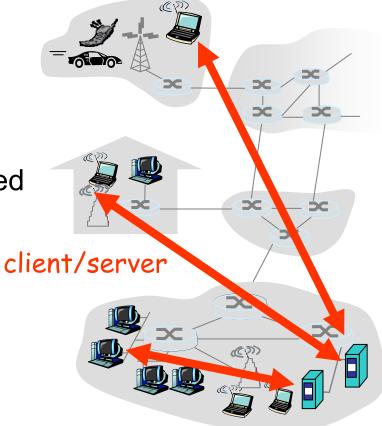

# **Client-server architecture**

#### server:

- always-on host
- permanent IP address
- server farms for scaling

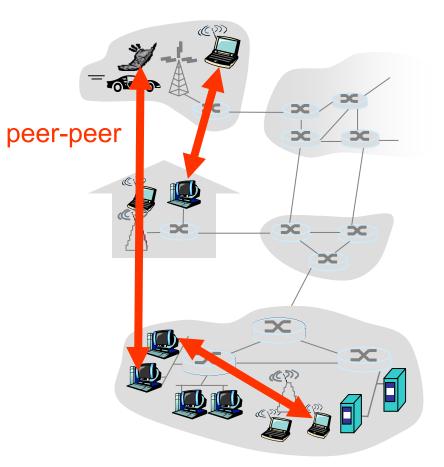

# clients:

- communicate with server
- may be intermittently connected
- may have dynamic IP addresses
- do not communicate directly with each other

- □ *no* always-on server
- arbitrary end systems
   directly communicate
- peers are intermittently connected and change IP addresses

Highly scalable but difficult to manage

# Hybrid of client-server and P2P

# Skype

- voice-over-IP P2P application
- centralized server: authenticates user, finds address of remote party
- client-client connection: direct (not through server)

Instant messaging

- chatting between two users is P2P
- centralized service: client presence detection/location
  - user registers its IP address with central server when it comes online
  - user contacts central server to find IP addresses of buddies

- Process: program running within a host.
- within same host, two processes communicate using inter-process communication (defined by OS).
- processes in different hosts
   communicate by exchanging
   messages

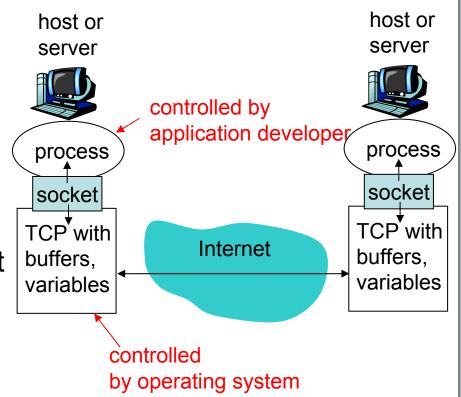

Client process: process that initiates communication

Server process: process that waits to be contacted

Note: applications with
 P2P architectures have
 client processes & server
 processes

- process sends/receives messages to/from its socket
- □ socket analogous to door
  - sending process shoves message out door
  - sending process relies on transport infrastructure on other side of door which brings message to socket at receiving process

API: (1) choice of transport protocol; (2) ability to fix a few parameters

# **Addressing processes**

- to receive messages, process must have *identifier*
- host device has unique 32-bit IP address
- Q: does IP address of host on which process runs suffice for identifying the process?
  - <u>A</u>: No, *many* processes can be running on same host

- identifier includes both IP address and port numbers associated with process on host.
- □ Example port numbers:
  - HTTP server: 80
  - Mail server: 25
- to send HTTP message to gaia.cs.umass.edu web server:
  - IP address: 128.119.245.12
  - Port number: 80

# Application-layer protocol defines

- □ Types of messages exchanged,
  - e.g., request, response
- Message syntax:
  - what fields in messages & how fields are delineated
- Message semantics
  - meaning of information in fields
- Rules for when and how processes send & respond to messages

# Public-domain protocols:

- □ defined in RFCs
- □ allows for interoperability
- □ e.g., HTTP, SMTP

# Proprietary protocols:

□ e.g., Skype

# What transport service does an application need?

#### Data loss

- □ some applications (e.g., audio) can tolerate some loss
- other applications (e.g., file transfer, telnet) require 100% reliable data transfer

# Timing

- some applications (e.g., Internet telephony, interactive games) require low delay to be "effective"
- frequently the applications also need timestamps (e.g. specifying playout time)

# Throughput

- some applications (e.g., multimedia) require minimum amount of throughput to be "effective"
- other applications ("elastic apps") make use of whatever throughput they get

#### Security

□ Encryption, data integrity, ...

	Application	Data loss	Throughput	Time Sensitive
_	file transfer	no loss	elastic	no
_	e-mail	no loss	elastic	no
$\overline{V}$	leb documents	no loss	elastic	no
real-tiī	me audio/video	loss-tolerant	audio: 5kbps-1Mbps video:10kbps-5Mbps	yes, 100's msec
	ed audio/video	loss-tolerant	same as above	yes, few secs
inte	eractive games	loss-tolerant	few kbps up	yes, 100's msec
inst	ant messaging	no loss	elastic	yes and no

# Internet transport protocols services

## TCP service:

- connection-oriented: setup required between client and server processes
- reliable transport between sending and receiving process
- flow control: sender won't overwhelm receiver
- congestion control: throttle sender when network overloaded
- does not provide: timing, minimum throughput guarantees, security

#### <u>UDP service:</u>

- unreliable data transfer
   between sending and receiving
   process
- does not provide: connection setup, reliability, flow control, congestion control, timing, throughput guarantee, or security

Q: why bother? Why is there a UDP?

Applic	ation	Application layer protocol	Underlying transport protocol
e	-mail	SMTP [RFC 2821]	ТСР
remote terminal ac	cess	Telnet [RFC 854]	TCP
	Web	HTTP [RFC 2616]	ТСР
file tra	nsfer	FTP [RFC 959]	TCP
streaming multin	nedia	HTTP (e.g., Youtube),	TCP or UDP
		RTP [RFC 1889]	
Internet telep	hony	SIP, RTP, proprietary	
	-	(e.g., Skype)	typically UDP

Principles of network applications

## Web and HTTP

DNS

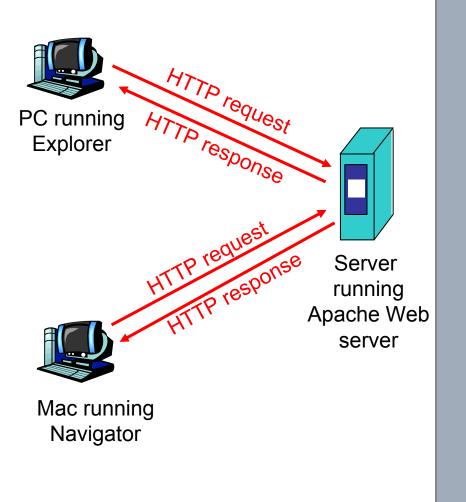

□ P2P applications

□ Summary

HTTP: hypertext transfer protocol

- Web's application layer protocol
- □ client/server model
  - *client:* browser that requests, receives, "displays" Web objects
  - server: Web server sends objects in response to requests

# **HTTP overview (continued)**

## HTTP uses TCP:

- client initiates TCP connection (creates socket) to server at port 80
- server accepts TCP
   connection from client
- HTTP messages (applicationlayer protocol messages)
   exchanged between browser (HTTP client) and Web server (HTTP server)
- http1.0: TCP connection
   closed after HTTP response

## HTTP is "stateless"

- server maintains no information about past client requests
  - Protocols that maintain "state" are complex!
  - past history (state) must be maintained
  - if server/client crashes, their views of "state" may be inconsistent, must be reconciled

## Nonpersistent HTTP (v1.0)

 At most one object is sent over a TCP connection.

#### Persistent HTTP (v1.1)

 Multiple objects can be sent over single TCP connection between client and server.

#### Suppose user enters URL

www.someSchool.edu/someDepartment/home.index (

1a. HTTP client initiates TCP connection to HTTP server (process) at www.someSchool.edu on port 80

2. HTTP client sends HTTP request message (containing URL) into TCP connection socket. Message indicates that client wants object someDepartment/home.index (contains text, references to 10 jpeg images)

 1b. HTTP server at host
 www.someSchool.edu waiting for TCP connection at port 80. "accepts" connection, notifying client

3. HTTP server receives request message, forms *response message* containing requested object, and sends message into its socket

5. HTTP client receives
 response message
 containing html file, displays
 html. Parsing html file, finds
 10 referenced jpeg objects

**4.** HTTP server closes TCP connection.

6. Steps 1-5 repeated for each of 10 jpeg objects

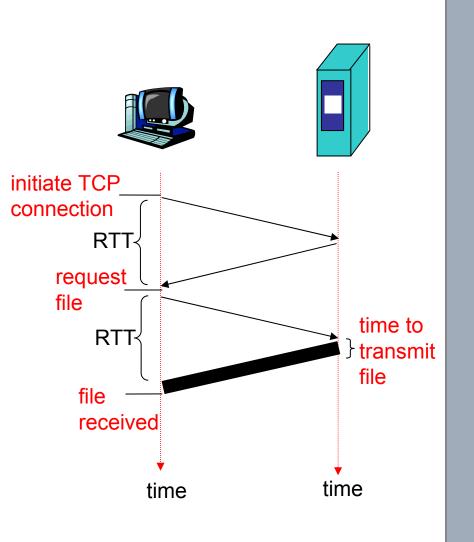

# **Non-Persistent HTTP: Response time**

Definition of RTT: time for a small packet to travel from client to server and back.

# Response time:

- one RTT to initiate TCP connection
- one RTT for HTTP request and first few bytes of HTTP response to return
- □ file transmission time

total = 2RTT+ transmit time

## Nonpersistent HTTP issues:

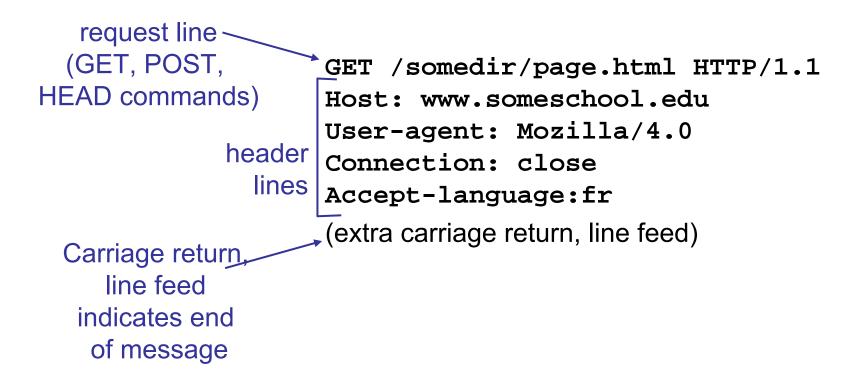

- requires 2 RTTs per object
- OS overhead for *each* TCP connection
- browsers often open parallel TCP connections to fetch referenced objects

#### Persistent HTTP

- server leaves connection
   open after sending response
- subsequent HTTP messages
   between same client/server
   sent over open connection
- client sends requests as soon as it encounters a referenced object
- as little as one RTT for all the referenced objects

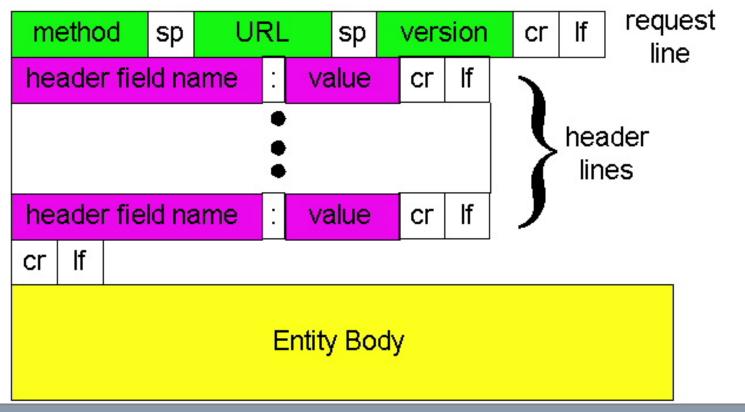

- □ two types of HTTP messages: *request*, *response*
- □ HTTP request message:
  - ASCII (human-readable format)

# HTTP request message: general format

```
GET /somedir/page.html HTTP/1.1
Host: www.someschool.edu
User-agent: Mozilla/4.0
Connection: close
Accept-language:fr
(extra carriage return, line feed)
```

## Post method:

- Web page often includes form input
- Input is uploaded to server in entity body

# URL method:

- Uses GET method
- Input is uploaded in URL field of request line:

www.somesite.com/animalsearch?monkeys&banana

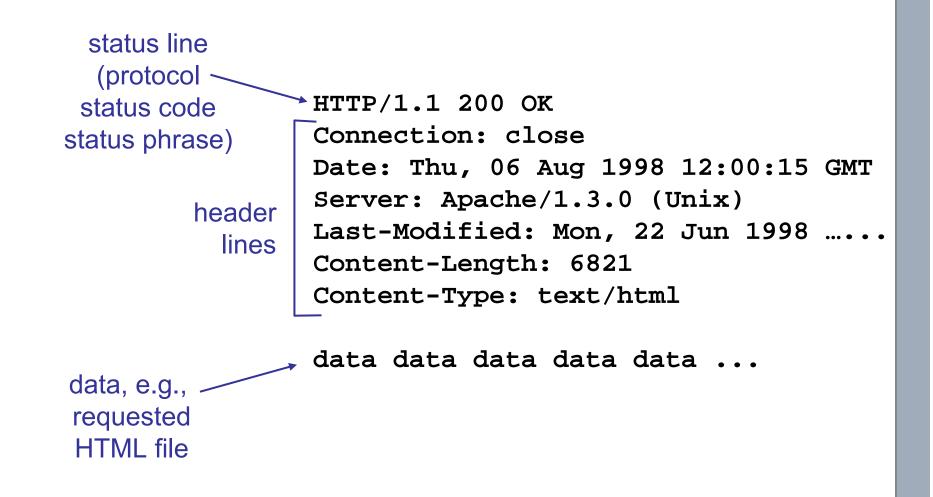

## <u>HTTP/1.0</u>

- 🛛 GET
- POST
- HEAD
  - asks server to leave requested object out of response

# <u>HTTP/1.1</u>

- □ GET, POST, HEAD
- PUT
  - uploads file in entity body to path specified in URL field
- DELETE
  - deletes file specified in the URL field

In first line in server: client response message
 A few sample codes:

#### 200 OK

- request succeeded, requested object later in this message
- 301 Moved Permanently
  - requested object moved, new location specified later in this message (Location:)
- 400 Bad Request
  - request message not understood by server
- 404 Not Found
  - requested document not found on this server
- 505 HTTP Version Not Supported

1. Telnet to your favorite Web server:

telnet cis.poly.edu 80

Opens TCP connection to port 80 (default HTTP server port) at cis.poly.edu. Anything typed in sent to port 80 at cis.poly.edu

2. Type in a GET HTTP request:

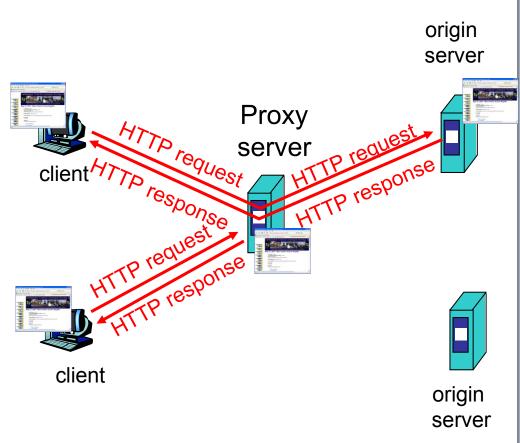

GET /~ross/ HTTP/1.1 Host: cis.poly.edu By typing this in (hit carriage return twice), you send this minimal (but complete) GET request to HTTP server

3. Look at response message sent by HTTP server!

# Web caches (proxy server)

- Goal: satisfy client request without involving origin server
- user sets browser: Web accesses via cache
- browser sends all HTTP requests to cache
  - object in cache: cache returns object
  - else cache requests object from origin server, then returns object to client

# More about Web caching

- cache acts as both client and server
- typically cache is installed by ISP (university, company, residential ISP)

## Why Web caching?

- reduce response time for client request
- reduce traffic on an institution's access link.
- Internet dense with caches: enables "poor" content providers to effectively deliver content (but so does P2P file sharing)

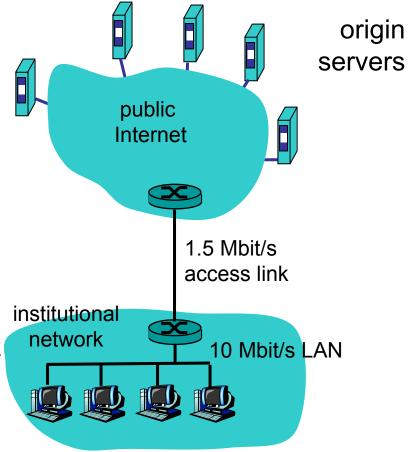

## **Assumptions**

- □ average object size = 100.000 bits
- avg. request rate from institution's
   browsers to origin servers = 15/sec
- delay from institutional router to any origin server and back to router = 2 sec

## **Consequences**

- traffic intensity (utilization) on LAN
   = 15%
- traffic intensity (utilization) on access link
   = 100%
- □ total delay
  - = Internet delay + access delay + LAN delay
  - = 2 sec + minutes + milliseconds

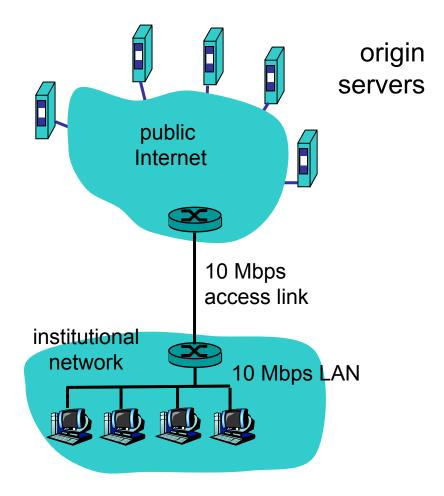

### possible solution

 increase bandwidth of access link to, say, 10 Mbps

#### <u>consequence</u>

- $\Box$  utilization on LAN = 15%
- $\Box$  utilization on access link = 15%
- Total delay = Internet delay + access delay + LAN delay
- = 2 sec + msecs + msecs
- □ often a costly upgrade

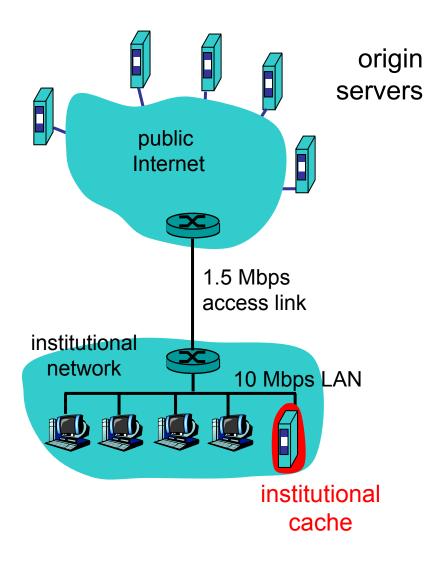

# Example (cont)

### possible solution: install cache

□ suppose hit rate is 0.4

### <u>consequence</u>

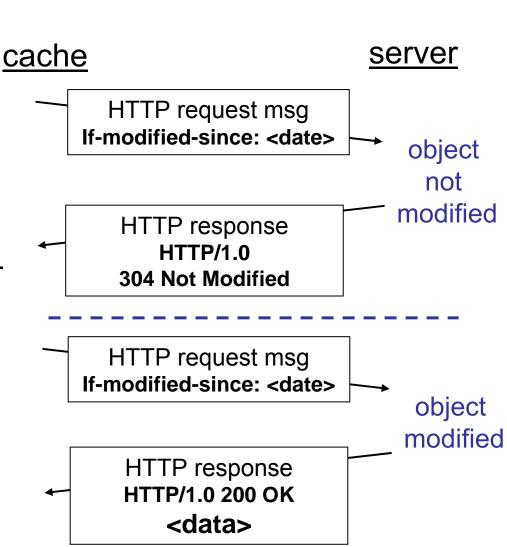

- 40% requests will be satisfied almost immediately
- 60% requests satisfied by origin server
- utilization of access link reduced to 60%, resulting in negligible delays (say 10 msec)
- □ total average delay
  - = 60%\*{ Internet delay + access delay + LAN delay}
    - + 40% \* milliseconds
  - = 0.6\*(2.01) sec + 0.4\*milliseconds
  - ≈ 1.2 secs

- Goal: don't send object if cache has up-to-date cached version
- server: response contains no object if cached copy is up-todate:

HTTP/1.0 304 Not Modified

Principles of network applications

□ Web and HTTP

### DNS

□ P2P applications

□ Summary

## **DNS: Domain Name System**

People: many identifiers:

 Social Secuity Number, name, passport #

## Internet hosts, routers:

- IP address (32 bit) used for addressing datagrams
- "name", e.g.,
   ww.yahoo.com used by
   humans
- Q: map between IP addresses and name ?

## Domain Name System:

- distributed database implemented in hierarchy of many name servers
- application-layer protocol host, routers, name servers to communicate to resolve names (address/name translation)
  - note: core Internet function, implemented as application-layer protocol
  - complexity at network's "edge"

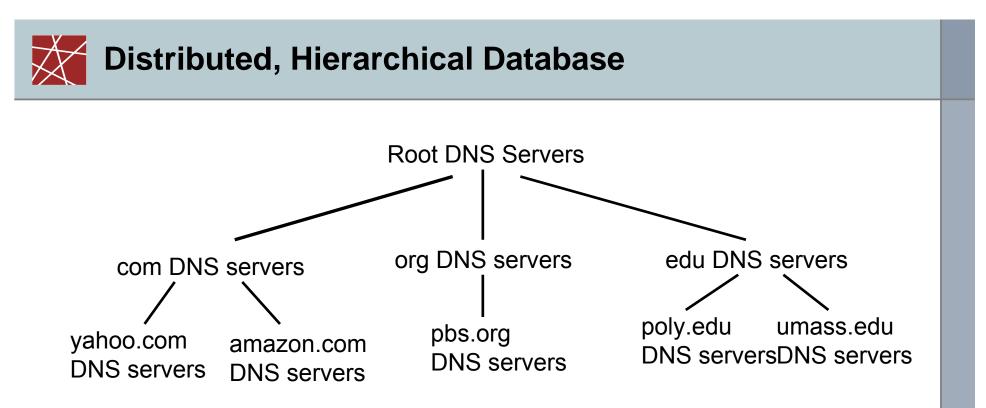

### Why not centralize DNS?

- □ single point of failure
- □ traffic volume
- □ distant centralized database □
- □ maintenance

doesn't scale!

### **DNS** services

- hostname to IP address translation
- tabase 😐 host aliasing
  - canonical name
  - alias names
  - mail server aliasing
    - mnemonic host name desired
    - MX record allows mnemonic host name reused for mail server
  - Ioad distribution
    - replicated Web servers: set of IP addresses for one canonical name

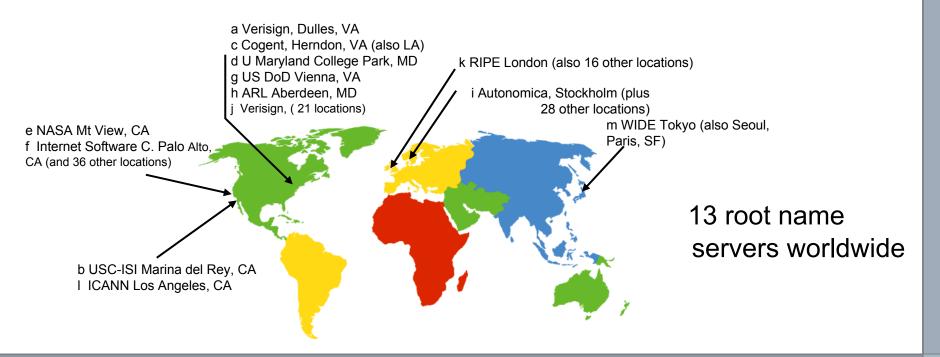

Client wants IP for www.amazon.com; 1st approx:

- □ client queries a root server to find com DNS server
- client queries com DNS server to get amazon.com DNS server
- client queries amazon.com DNS server (authorative DNS server – configured by original source) to get IP address for www.amazon.com

- □ contacted by local name server that can not resolve name
- □ root name server:
  - contacts authoritative name server if name mapping not known
  - gets mapping
  - returns mapping to local name server

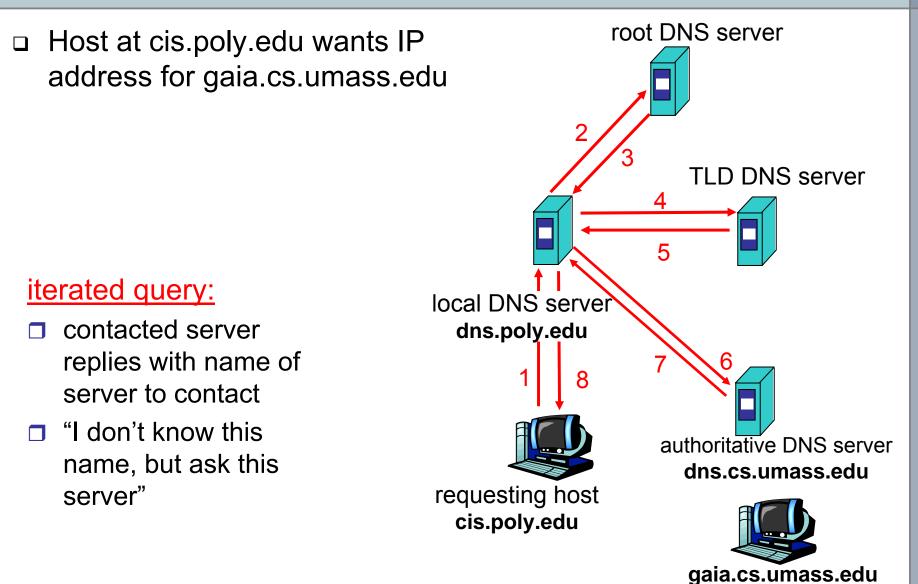

- □ Top-level domain (TLD) servers:
  - responsible for com, org, net, edu, etc, and all top-level country domains uk, fr, ca, jp.
  - organisations hosting TLD servers:
    - Network Solutions maintains servers for com TLD
    - Educause for edu TLD
- □ Authoritative DNS servers:
  - organization's DNS servers, providing authoritative hostname to IP mappings for organization's servers (e.g., Web, mail).
  - can be maintained by organization or service provider

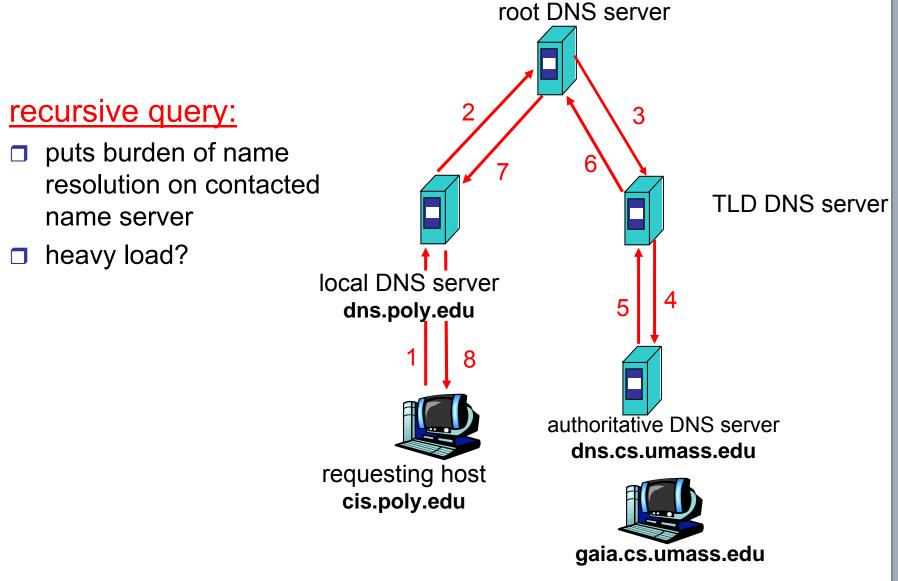

- □ does not strictly belong to hierarchy
- □ each ISP (residential ISP, company, university) has one.
  - also called "default name server"
- when host makes DNS query, query is sent to its local DNS server
  - acts as proxy, forwards query into hierarchy

□ once (any) name server learns mapping, it *caches* mapping

- cache entries timeout (disappear) after some time
- TLD servers typically cached in local name servers
  - Thus root name servers not often visited
- update/notify mechanisms
  - RFC 2136
  - http://www.ietf.org/html.charters/dnsind-charter.html
  - "notify" mechanism: primary sends a message to known secondaries. for fast convergence of servers

DNS: distributed db storing resource records (RR)

RR format: (name, value, type, ttl)

- □ Type=A
  - name is hostname
  - value is IP address
- □ Type=NS
  - name is domain (e.g. foo.com)
  - value is hostname of authoritative name server for this domain

□ Type=CNAME

- name is alias name for some "canonical" (the real) name
- e.g.: www.ibm.com is really servereast.backup2.ibm.com (canonical name)

□ Type=MX

 value is name of mailserver associated with name

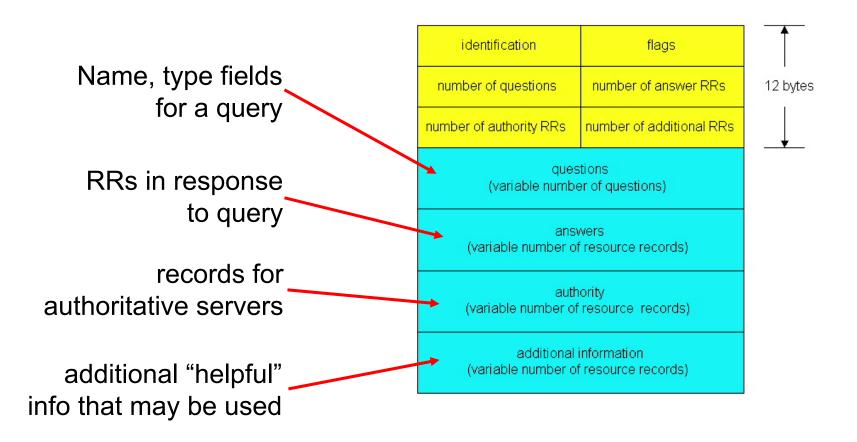

DNS protocol : query and reply messages, both with same message format

### message header

- identification: 16 bit # for query, reply to query uses same #
- □ flags:
  - query or reply
  - recursion desired
  - recursion available
  - reply is authoritative

identification	flags	
number of questions	number of answer RRs	12 bytes
number of authority RRs	number of additional RRs	Ļ
ques (variable numbe		
ansv (variable number of		
auth (variable number of		
additional (variable number of		

- □ example: new startup "Network Utopia"
- register name networkuptopia.com at DNS registrar (e.g., Network Solutions)
  - provide names, IP addresses of authoritative name server (primary and secondary)
  - registrar inserts two RRs into com TLD server:

```
(networkutopia.com, dns1.networkutopia.com,
NS)
```

(dnsl.networkutopia.com, 212.212.212.1, A)

create authoritative server
 Type A record for www.networkuptopia.com
 Type MX record for networkutopia.com

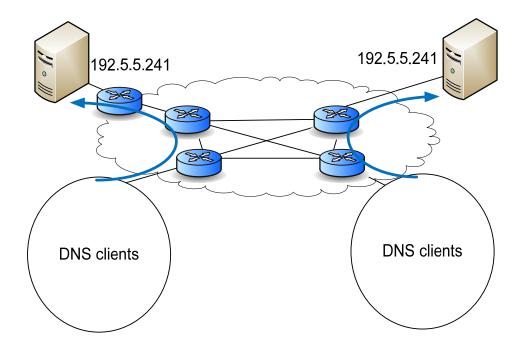

- □ 13 root servers (A to M)
- But number of physical servers in total is higher
- □ and increasing:
  - 191 by Oct. 2009
  - 229 by Oct. 2010

- □ Multiple servers can be made reachable under the same IP address
- □ Via *IP anycast*
- □ E.g. F-root server (IPv4: 192.5.5.241; IPv6: 2001:500:2f::f)

- □ IP anycast used for DNS since 2002 for root servers and many TLDs
- → High robustness
- → New servers can be easily added without updating the DNS clients.

- □ TTL not specified in the standard (RFC 1034-1035)
- □ But in practice TTLs often up to 24 hours
- Records for TLDs are provided by root servers and typically stored even for 48 hours
- Caching typically improves lookup performance
- □ Caching relieves upper nodes in the hierarchy (root + TLDs)
- □ Massive caching makes it difficult to:
  - Dynamically react to current load
  - Migrate services
  - → TTLs of 60 s are typical today (e.g. amazon.com)

#### □ e.g. amazon.com

user@host:~\$ dig amazon.com

- ; <<>> DiG 9.6.1-P2 <<>> amazon.com
- ;; global options: +cmd
- ;; Got answer:
- ;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 42197
- ;; flags: qr rd ra; QUERY: 1, ANSWER: 3, AUTHORITY: 7, ADDITIONAL: 9

;; QUESTION SECTION:

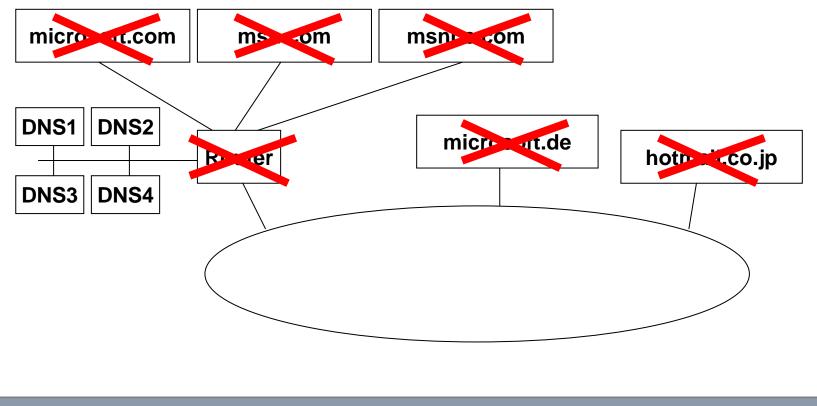

;amazon.com.			IN	A	
;; ANSWER SECTION:					
amazon.com.	60	IN	A	72.21.210.250	
amazon.com.	60	IN	A	207.171.166.252	
amazon.com.	60	IN	A	72.21.207.65	

IN2097 - Master Course Computer Networks, WS 2010/2011

# DoS-Attack targeting Microsoft in January 2001

- First: router problem → Microsoft's websites and services were down on January 23rd 2001
- The damage was surprisingly large

- □ Web servers are be running
- But DNS failure leads to service failure
- → Need to deploy multiple DNS authorative servers
- → In different networks

Principles of network applications

Web and HTTP

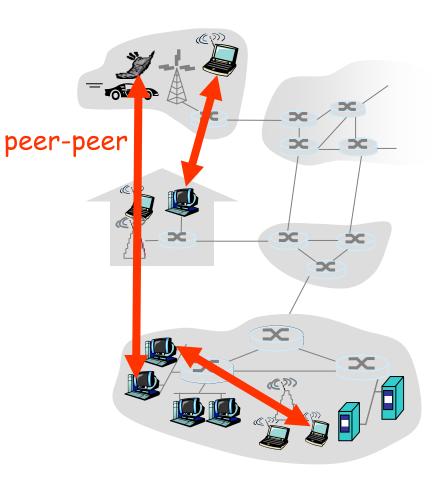

DNS

P2P applications

□ Summary

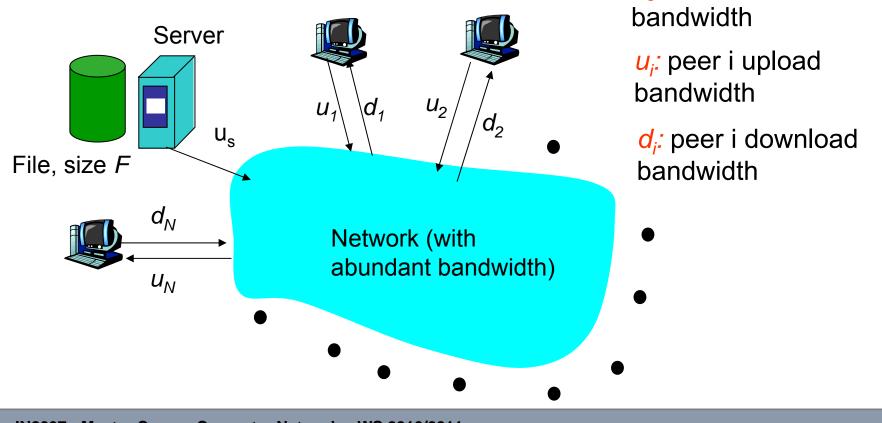

- □ *no* always-on server
- arbitrary end systems directly communicate
- peers are intermittently connected and change IP addresses
- □ <u>Three topics:</u>
  - File distribution
  - Searching for information
  - Case Study: Skype

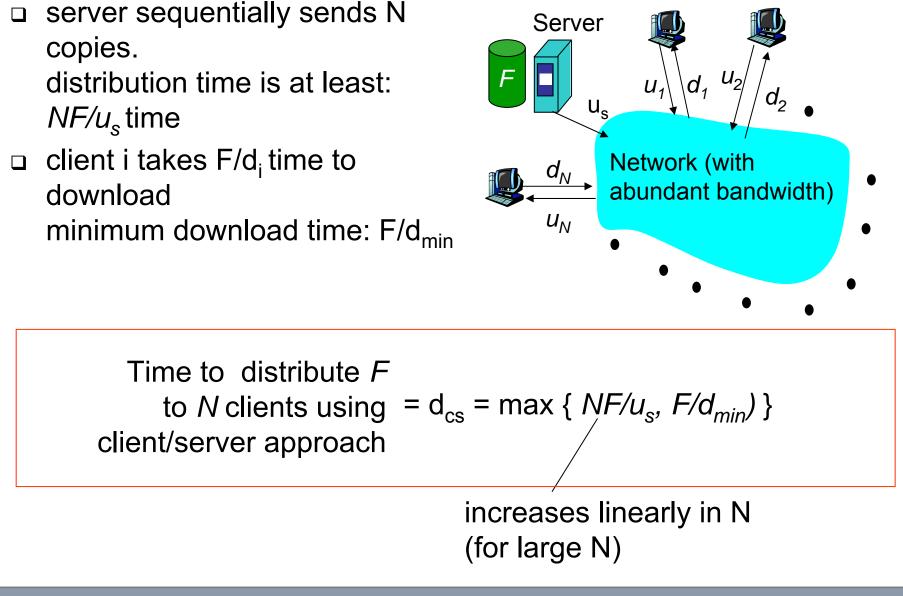

Question : How much time to distribute file from one server to N peers?

us: server upload

## File distribution time: server-client

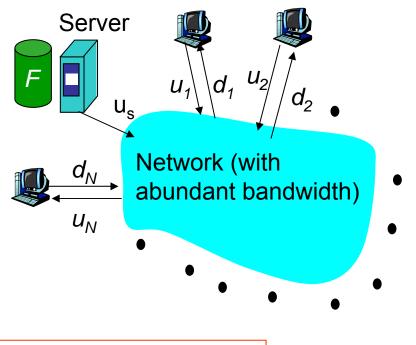

# File distribution time: P2P

- □ server must send one copy:  $F/u_s$  time
- client i takes F/d<sub>i</sub> time to download
- NF bits must be downloaded (aggregate)

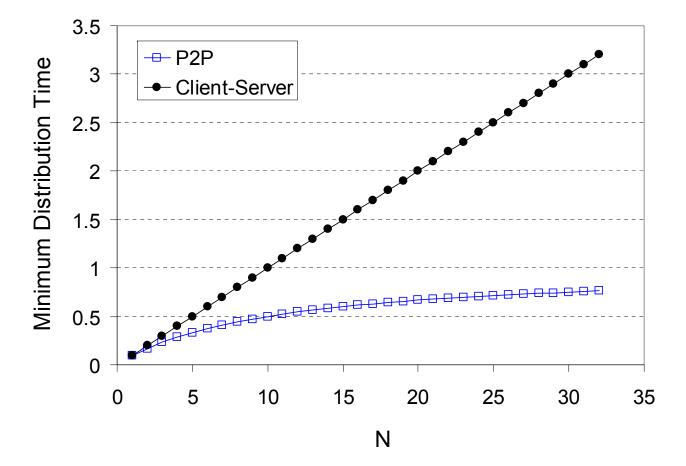

fastest possible upload rate:  $u_s + Su_i$ 

$$\mathsf{d}_{\mathsf{P2P}} = \max\left\{\textit{F/u}_{\mathsf{s}}, \textit{F/d}_{\textit{min}}, \textit{NF/(u_{\mathsf{s}} + \Sigma u_{\mathsf{i}})}\right\}$$

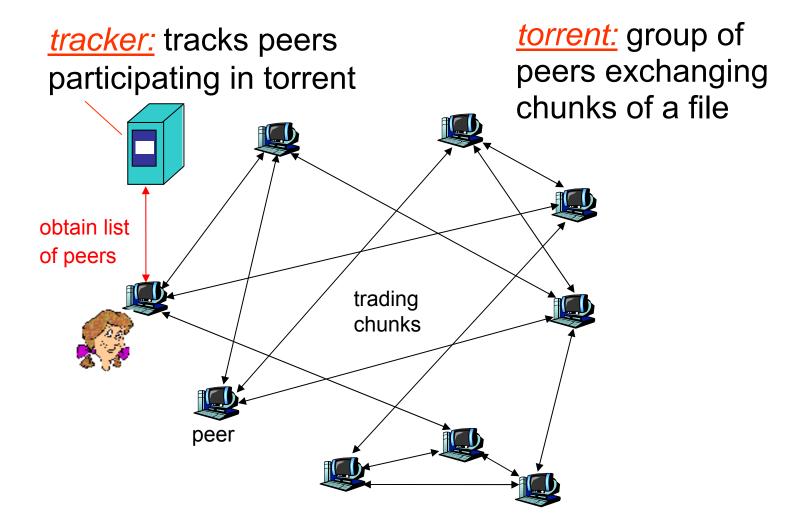

Client upload rate = u, F/u = 1 hour,  $u_s = 10u$ ,  $d_{min} \ge u_s$ 

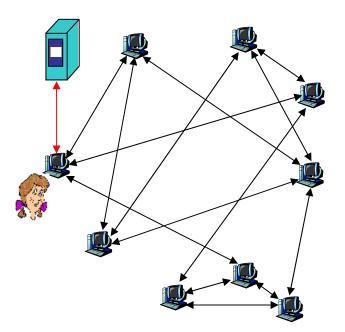

## □ P2P file distribution

- □ file divided into 256KB *chunks*.
- □ peer joining torrent:
  - has no chunks, but will accumulate them over time
  - registers with tracker to get list of peers, connects to subset of peers ("neighbors")
- while downloading, peer uploads chunks to other peers.
- □ peers may come and go
- once peer has entire file, it may (selfishly) leave or (altruistically) remain

## **Pulling Chunks**

- at any given time, different peers have different subsets of file chunks
- periodically, a peer (Alice)
   asks each neighbor for list of
   chunks that they have.
- Alice sends requests for her missing chunks
  - rarest first

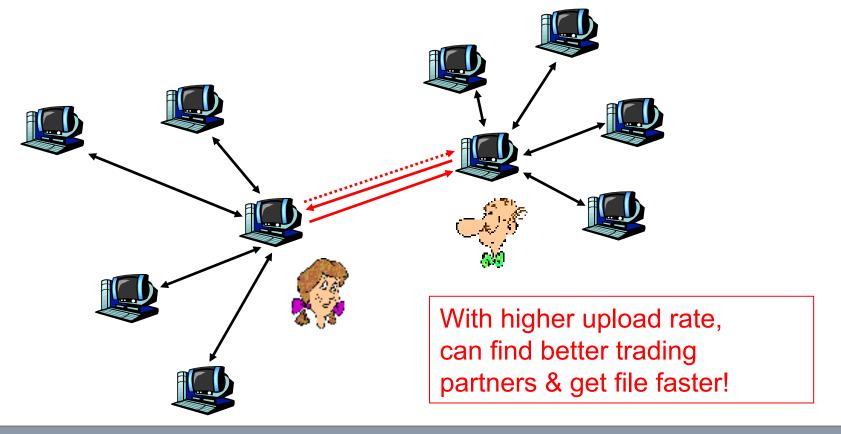

### Sending Chunks: tit-for-tat

- Alice sends chunks to four neighbors currently sending her chunks at the highest rate
  - re-evaluate top 4 every 10 secs
- every 30 secs: randomly select another peer, starts sending chunks
  - newly chosen peer may join top 4
  - "optimistically unchoke"

(1) Alice "optimistically unchokes" Bob

- (2) Alice becomes one of Bob's top-four providers; Bob reciprocates
- (3) Bob becomes one of Alice's top-four providers

# **Distributed Hash Table (DHT)**

- □ DHT = distributed P2P database
- Database has (key, value) pairs;
  - key: social security number; value: human name
  - key: content identifier; value: IP address
- □ Peers query DB with key
  - DB returns values that match the key
- □ Peers can also insert (key, value) peers

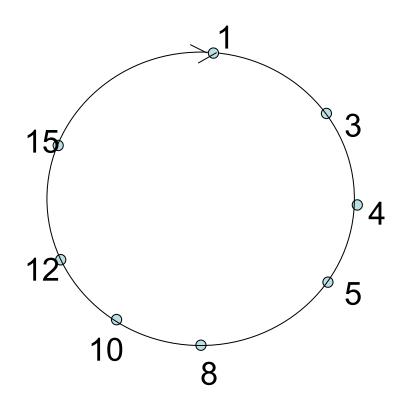

□ Assign integer identifier to each peer in range  $[0,2^{n}-1]$ .

- Each identifier can be represented by n bits.
- □ Require each key to be an integer in same range.
- □ To get integer keys, hash original key.
  - eg, key = h("Led Zeppelin IV")
  - This is why they call it a distributed "hash" table

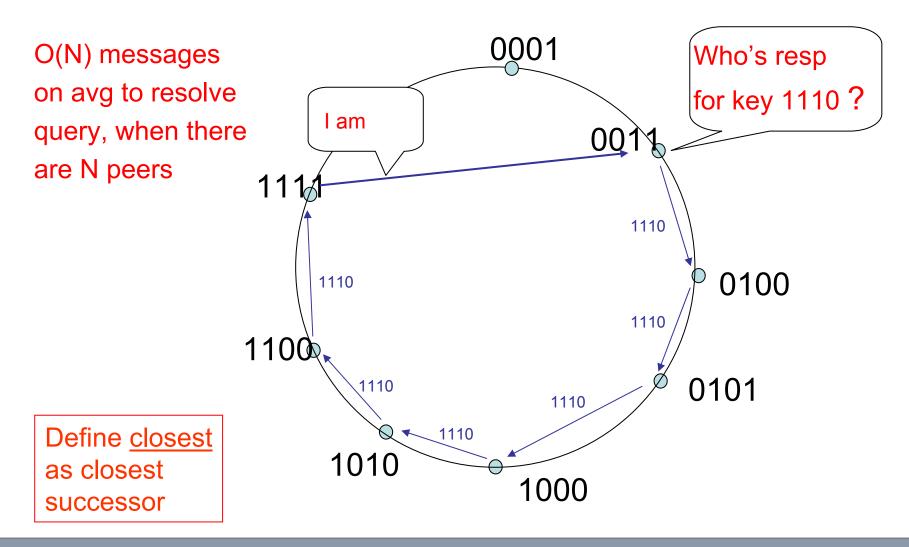

- □ Central issue:
  - Assigning (key, value) pairs to peers.
- □ Rule: assign key to the peer that has the closest ID.
- Convention in lecture: closest is the immediate successor of the key.
- □ Example: n=4; peers: 1,3,4,5,8,10,12,14;
  - key = 13, then successor peer = 14
  - key = 15, then successor peer = 1

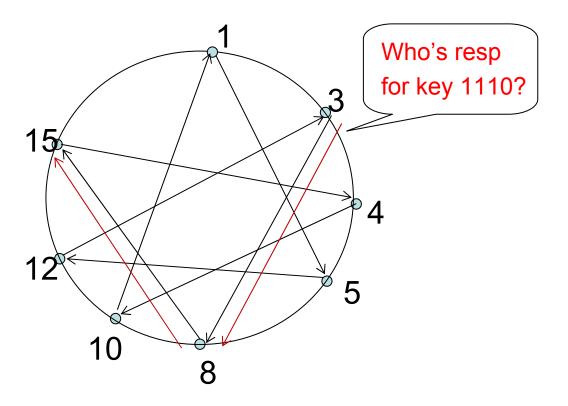

Each peer *only* aware of immediate successor and predecessor.
 "Overlay network"

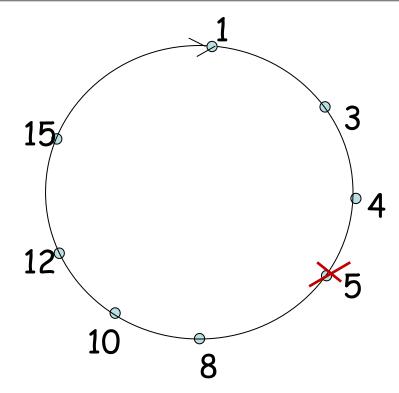

- Each peer keeps track of IP addresses of predecessor, successor, short cuts.
- Shortcuts reduce required number of query messages (e.g. from 6 to 2).
- Possible to design shortcuts so O(log N) neighbors, O(log N) messages in query

•To handle peer churn, require each peer to know the IP address of its two successors.

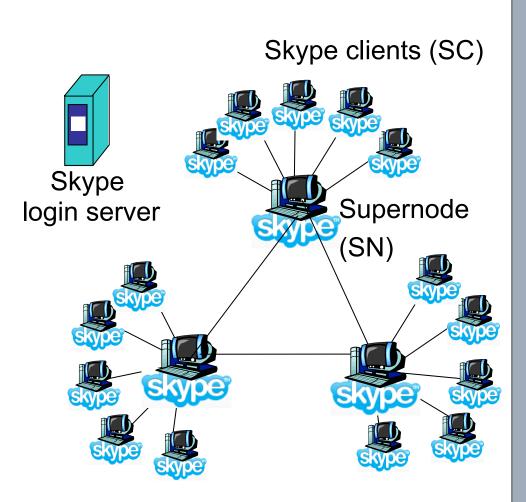

• Each peer periodically pings its two successors to see if they are still alive.

- □ Peer 5 abruptly leaves
- Peer 4 detects; makes 8 its immediate successor; asks 8 who its immediate successor is; makes 8's immediate successor its second successor.
- □ What if peer 13 wants to join?

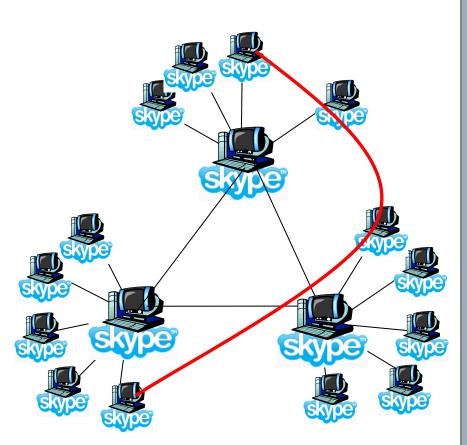

## P2P Case study: Skype

- inherently P2P: pairs of users communicate.
- proprietary application-layer protocol (inferred via reverse engineering)
- hierarchical overlay with Supernodes
- Index maps usernames to IP addresses; distributed over Supernodes

- Problem when both Alice and Bob are behind "NATs".
  - NAT prevents an outside peer from initiating a call to insider peer
- □ Solution:
  - Using Alice's and Bob's Supernodes, Relay is chosen
  - Each peer initiates session with relay.
  - Peers can now communicate through NATs via relay

Principles of network applications

□ Web and HTTP

DNS

□ P2P applications

**Summary** 

## network application level issues

- □ application architectures
  - client-server
  - P2P
  - hybrid
- □ application service requirements:
  - reliability, bandwidth, delay
- Internet transport service model
  - connection-oriented, reliable: TCP
  - unreliable, datagrams: UDP
- □ specific protocols:
  - HTTP
  - DNS
  - P2P: BitTorrent, Skype
- □ socket programming

# Most importantly: learned about protocols

□ typical request/reply message exchange:

- client requests info or service
- server responds with data, status code
- □ message formats:
  - headers: fields giving info about data
  - data: info being communicated
- □ Important themes:
- □ control vs. data messages
  - in-band, out-of-band
- □ centralized vs. decentralized
- □ stateless vs. stateful
- □ reliable vs. unreliable message transfer
- □ "complexity at network edge"
