# Cryptographic algorithms: outline

# Cryptographic algorithms: overview

- During this course two main applications of cryptographic algorithms are of principal interest:
  - *Encryption* of data: transforms plaintext data into ciphertext in order to conceal its meaning
  - *Signing* of data: computes a *check value* or *digital signature* of a given plain- or ciphertext, that can be verified by some or all entities who are able to access the signed data
- Some cryptographic algorithms can be used for both purposes, some are only secure and / or efficient for one of them.
- Principal categories of cryptographic algorithms:
  - *Symmetric cryptography* using 1 key for en-/decryption or signing/checking
  - *Asymmetric cryptography* using 2 different keys for en-/decryption or signing/checking
  - *Cryptographic hash functions* using 0 keys (the “key” is not a separate input but “appended” to or “mixed” with the data).

## Attacking cryptography (1): Cryptanalysis

- *Cryptanalysis* is the process of attempting to discover the plaintext and / or the key
- Types of cryptanalysis:
  - *Ciphertext only*: work on ciphertext only; hope that specific patterns of the plaintext have remained in the ciphertext (frequencies of letters, digraphs, etc.)
  - *Known ciphertext / plaintext pairs*
  - *Chosen plaintext or chosen ciphertext*
  - Newer developments: *differential cryptanalysis, linear cryptanalysis*
- Cryptanalysis of public key cryptography:
  - The fact that one key is publicly exposed may be exploited
  - Public key cryptanalysis is more aimed at breaking the cryptosystem itself and is closer to pure mathematical research than to classic cryptanalysis
  - Important directions:
    - Computation of discrete logarithms
    - Factorization of large integers

## Attacking cryptography (2): brute force attack

- The *brute force attack* tries every possible key until it finds an intelligible plaintext:
  - Every cryptographic algorithm can in theory be attacked by brute force
  - On average, half of all possible keys will have to be tried

### Average Time Required for Exhaustive Key Search

Key Size [bit]	Number of keys	Time required at 1 encryption / $\mu\text{s}$	Time required at $10^6$ encryption/ $\mu\text{s}$
32	$2^{32} = 4.3 * 10^9$	$2^{31} \mu\text{s} = 35.8$ minutes	2.15 milliseconds
56	$2^{56} = 7.2 * 10^{16}$	$2^{55} \mu\text{s} = 1142$ years	10.01 hours
128	$2^{128} = 3.4 * 10^{38}$	$2^{127} \mu\text{s} = 5.4 * 10^{24}$ years	$5.4 * 10^{18}$ years

- 1 encryption /  $\mu\text{s}$ : 100 Clock cycles of a 100 MHz processor
- $10^6$  encryptions /  $\mu\text{s}$ : Clock cycles using 500 parallel 2GHz processors

## Attacking cryptography (3): How large is large?

### Reference Numbers Comparing Relative Magnitudes

Reference	Magnitude
Seconds in a year	$\approx 3 * 10^7$
Seconds since creation of solar system	$\approx 2 * 10^{17}$
Clock cycles per year (3 GHz computer)	$\approx 1 * 10^{17}$
Binary strings of length 64	$2^{64} \approx 1.8 * 10^{19}$
Binary strings of length 128	$2^{128} \approx 3.4 * 10^{38}$
Binary strings of length 256	$2^{256} \approx 1.2 * 10^{77}$
Number of 75-digit prime numbers	$\approx 5.2 * 10^{72}$
Electrons in the universe	$\approx 8.37 * 10^{77}$

## Classification of modern encryption algorithms

- ❑ The type of operations used for transforming plaintext to ciphertext:
  - *Substitution*, which maps each element in the plaintext (bit, letter, group of bits or letters) to another element
  - *Transposition*, which re-arranges elements in the plaintext
- ❑ The number of keys used:
  - *Symmetric ciphers*, which use the same key for en- / decryption
  - *Asymmetric ciphers*, which use different keys for en- / decryption
- ❑ The way in which the plaintext is processed:
  - *Stream ciphers* work on bit streams and encrypt one bit after another
  - *Block ciphers* work on blocks of width  $b$  with  $b$  depending on the specific algorithm.

# Basic Kryptographic Principles

## □ Substitution

- Individual characters are exchanged by other characters

### Types of substitution

- simple substitution: operates on single letters
- polygraphic substitution: operates on larger groups of letters
- monoalphabetic substitution: uses fixed substitution over the entire message
- polyalphabetic substitution: uses different substitutions at different sections of a message

## □ Transposition

- The position of individual characters changes (Permutation)

# Transposition: scytale

- Known as early as 7<sup>th</sup> century BC
- Principle:
  - Wrap parchment strip over a wooden rod of a fixed diameter and write letters along the rod.
  - Unwrap a strip and “transmit”
  - To decrypt, wrap a received over a wooden rod of the same diameter and read off the text.

- Example:

troops  
headii  
nthewe  
stneed  
moresu  
pplies

thnsm predd opoah nrlod eeis iedus

- Weakness:
  - Easy to break by finding a suitable matrix transposition.

# Monoalphabetic substitution: Atbash

Jeremiah 25:25

And all the kings of the north, far and near, one with another, and all the kingdoms of the world, which are upon the face of the earth: and the king of Sheshach shall drink after them.

Atbash code: reversed Hebrew alphabet.

Sheshach ⇒ ש ש כך ⇒ ל ב ב ⇒ Babel

# Monoalphabetic substitution: Caesar cipher

- Caesar code: left shift of alphabet by 3 positions.

- Example (letter of Cicero to Caesar):

MDEHV RSNQNRQNV PHDH XHVXNPRQNZP

HABES OPINIONIS MEAE TESTIMONIUM

- Weakness: a limited number of possible substitutions. Easy to break by brute force!

# Modern cryptography: S and P-boxes

S-box:

- ❑ Block-wise **substitution** of binary digits.
- ❑ Resistant to attacks for sufficiently large block size; e.g. for  $n=128$  it provides  $2^{128}$  possible mappings.

P-box:

- ❑ Block-wise **permutation** of binary digits.
- ❑ Realizes a simple **transposition** cipher with maximal entropy.
- ❑ Problem: straightforward attacks exist.

## Feistel network: a product cipher of S and P-boxes

- A revival of the idea of a product cipher.
  - A product cipher is a combination of simple ciphers (e.g. S-box and P-box) to make the cipher more secure.
  - Rounds: This combination may be applied multiple times.
- Multiple rounds provide a cryptographically strong polyalphabetic substitution.
- Combination of substitution with transposition provides protection against specific attacks (frequency analysis).
- Follows the theoretical principles outlined by C. Shannon in 1949: combines “confusion” with “diffusion” to attain maximal entropy of a cipher text.
  - Confusion: cipher text statistics depend in a very complex way on plaintext statistics (approach: substitution in different rounds)
  - Diffusion: each digit in plaintext and in key influence many digits of cipher text (approach: many rounds with transposition)

## A practical Feistel cipher

- ❑ A multiple-round scheme with separate keys per round.
- ❑ Goal: Encrypt plaintext block  $P = L_0 \mid R_0$
- ❑ Function  $f(K_i, R_{i-1})$  is algorithm-specific, usually a combination of permutations and substitutions.
- ❑ Invertible via a reverse order of rounds.
- ❑ 3 rounds suffice to achieve a pseudorandom permutation.
- ❑ 4 rounds suffice to achieve a strong pseudorandom permutation (i.e. it remains pseudorandom to an attacker with an oracle access to its inverse permutation).
- ❑ A foundation for a large number of modern symmetric ciphers: DES, Lucifer, Blowfish, RC5, Twofish, etc.

## Important properties of encryption algorithms

Consider, a sender is encrypting plaintext messages  $P_1, P_2, \dots$  to ciphertext messages  $C_1, C_2, \dots$

Then the following properties of the encryption algorithm are of special interest:

- *Error propagation* characterizes the effects of bit-errors during transmission of ciphertext on reconstructed plaintext  $P_1', P_2', \dots$ 
  - Depending on the encryption algorithm there may be one or more erroneous bits in the reconstructed plaintext per erroneous ciphertext bit
  
- *Synchronization* characterizes the effects of lost ciphertext data units on the reconstructed plaintext
  - Some encryption algorithms cannot recover from lost ciphertext and need therefore explicit re-synchronization in case of lost messages
  - Other algorithms do automatically re-synchronize after 0 to  $n$  ( $n$  depending on the algorithm) ciphertext bits

# Symmetric Encryption

- General description:
  - The same key  $K_{A,B}$  is used for enciphering and deciphering of messages:

- Notation
  - If  $P$  denotes the plaintext message,  $E(K_{A,B}, P)$  denotes the cipher text. The following holds:  $D(K_{A,B}, E(K_{A,B}, P)) = P$
  - Alternatively we sometimes write  $\{P\}_{K_{A,B}}$  or  $E_{K_{A,B}}(P)$  for  $E(K_{A,B}, P)$
- Symmetric encryption
  - $E_{K_{A,B}}$  is at least an injective, often a bijective function
  - $D_{K_{A,B}}$  is the inverse function of  $E_{K_{A,B}}$ :  $D_{K_{A,B}} = (E_{K_{A,B}})^{-1}$
- Examples: DES, 3DES, AES, Twofish, RC4

## Modes of Encryption

- ❑ Block ciphers operate on 128-256 bits. How can one encrypt longer messages? Answer:
  - A plaintext  $p$  is segmented in blocks  $p_1, p_2, \dots$  each of length  $b$  or of length  $j < b$  when payload length is smaller or not a multiple of  $b$ .  $b$  denotes the block size of the encryption algorithm.
  - The ciphertext  $c$  is the combination of  $c_1, c_2, \dots$  where  $c_i$  denotes the result of the encryption of the  $i^{\text{th}}$  block of the plaintext message
  - The entities encrypting and decrypting a message have agreed upon a key  $K$ .
- ❑ Modes where the plaintext is input to the block cipher. Examples:
  - Electronic Code Book Mode (ECB), Cipher Block Chaining Mode (CBC)
- ❑ Modes where the plaintext is XORed with the output of a block cipher
  - A pseudorandom stream of bits, called *key stream* is generated from the symmetric key  $K$  and a specific input per block, e.g.  $E(K, \text{"Block 1"}), E(K, \text{"Block 2"}), E(K, \text{"Block 3"}), \dots$
  - Examples
    - Output Feedback Mode (OFB), Counter Mode (CTR)

## Symmetric Block Ciphers - Modes of Encryption – ECB (1)

- *Electronic Code Book Mode (ECB):*
  - Every block  $p_i$  of length  $b$  is encrypted independently:  $c_i = E(K, p_i)$
  - A bit error in one ciphertext block  $c_i$  results in a completely wrongly recovered plaintext block  $p_i'$  (subsequent blocks are not affected)
  - Loss of synchronization does not have any effect if integer multiples of the block size  $b$  are lost.  
If any other number of bits are lost, explicit re-synchronization is needed.
  - Drawback: identical plaintext blocks are encrypted to identical ciphertext!

## Symmetric Block Ciphers - Modes of Encryption – CBC (1)

- *Cipher Block Chaining Mode (CBC)*:
  - Before encrypting a plaintext block  $p_i$ , it is XORed ( $\oplus$ ) with the preceding ciphertext block  $c_{i-1}$ :
    - $c_i = E(K, c_{i-1} \oplus p_i)$
    - $p_i' = c_{i-1} \oplus D(K, c_i)$
  - Both parties agree on an *initial value* for  $c_i$  called *Initialization Vector (IV)*
    - $c_0 = IV$
- **Properties**:
  - Advantage: identical plaintext blocks are encrypted to non-identical ciphertext.
  - Error propagation:
    - A distorted ciphertext block results in two distorted plaintext blocks, as  $p_i'$  is computed using  $c_{i-1}$  and  $c_i$
  - Synchronisation:
    - If the number of lost bits is a multiple integer of  $b$ , one additional block  $p_{i+1}$  is misrepresented before synchronization is re-established.  
If any other number of bits are lost explicit re-synchronization is needed.
  - Applicable for
    - Encryption
    - Integrity check: use last block of CBC as Message Authentication Code (MAC)

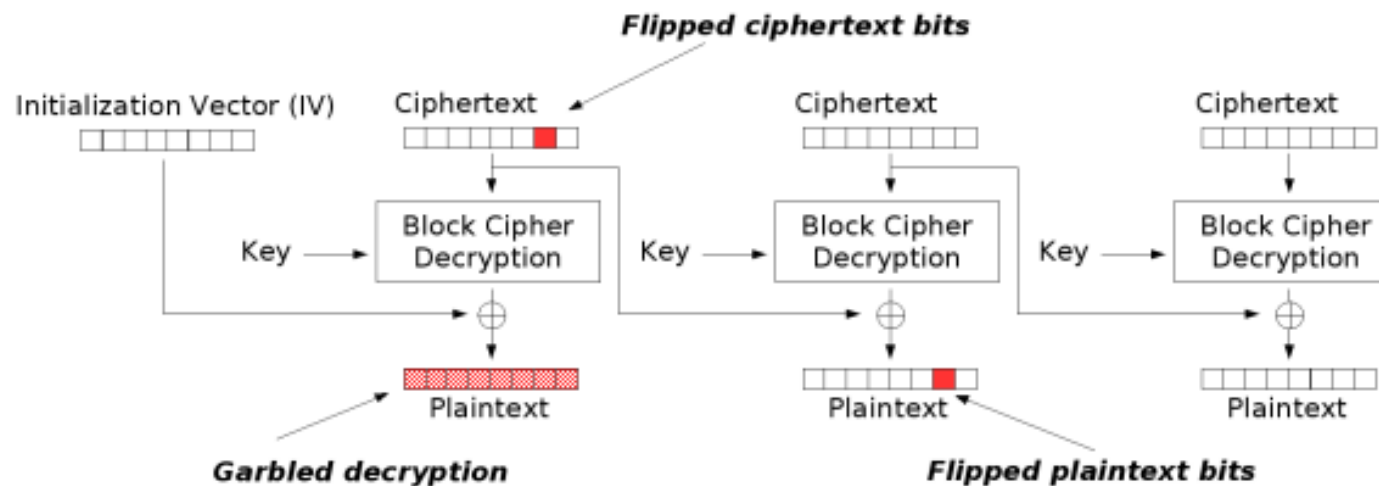

## Symmetric Block Ciphers - Modes of Encryption – CBC (2)

# CBC Error Propagation

- A distorted ciphertext block results in two distorted plaintext blocks, as  $p_i'$  is computed using  $c_{i-1}$  and  $c_i$

## Symmetric Block Ciphers - Modes of Encryption – OFB (1)

- *Output Feedback Mode (OFB):*
  - The block encryption algorithm is used to generate a key stream that depends only on  $K$  and  $IV$ 
    - $K_0 = IV$
    - $K_i = E(K, K_{i-1})$
    - $C_i = P_i \oplus K_i$
  - The plaintext blocks are XORed with the pseudo-random sequence to obtain the ciphertext and vice versa

# Symmetric Block Ciphers - Modes of Encryption – OFB (2)

## Symmetric Block Ciphers - Modes of Encryption – OFB (3)

- Properties of OFB:
  - Error propagation:
    - Single bit errors result only in single bit errors  $\Rightarrow$  no error multiplication
  - Synchronisation:
    - If some bits are lost explicit re-synchronization is needed
  - Advantage:
    - The pseudo-random sequence can be pre-computed in order to keep the impact of encryption to the end-to-end delay low
  - Drawbacks:
    - It is possible for an attacker to manipulate specific bits of the plaintext  
 $\rightarrow$  However, additional cryptographic means are can be used for message integrity

## Symmetric Block Ciphers – Modes of Encryption - CTR (1)

- *Counter Mode (CTR)*
  - The block encryption algorithm is used to generate a key stream that depends on  $K$  and a counter function  $ctr_i$ .
  - The counter function can be simply an increment modulo  $2^w$ , where  $w$  is a convenient register width, e.g.
    - $ctr_i = \text{Nonce} || i$
  - The counter function does not provide any security other than the uniqueness of the input to the block cipher function  $E$
  - The plaintext blocks are XORed with the pseudo-random sequence to obtain the ciphertext and vice versa
  - Putting everything together:
    - $K_i = E(K, \text{Nonce} || i)$
    - $C_i = P_i \oplus K_i$

CTR

## Symmetric Block Ciphers – Modes of Encryption - CTR (3)

- Properties of CTR:
  - Error propagation:
    - Single bit errors result only in single bit errors  $\Rightarrow$  no error multiplication
  - Synchronisation:
    - If some bits are lost explicit re-synchronization is needed.
  - Advantage:
    - The key stream can be pre-computed in order to keep the impact of encryption to the end-to-end delay low.
    - The computation of the key stream can be parallelized.
  - Drawbacks:
    - It is possible for an attacker to manipulate specific bits of the plaintext  
 $\rightarrow$  However, additional cryptographic means are required for message integrity
