# Quality of Service Support

# Providing Multiple Classes of Service

- ❑ Traditional Internet approach: making the best of best effort service
  - one-size fits all service model
- ❑ Alternative approach: multiple classes of service
  - partition traffic into classes
  - network treats different classes of traffic differently (analogy: VIP service vs regular service)
- ❑ granularity:  
differential service among multiple classes, not among individual connections
- ❑ history:  
ToS bits in IP header

# Delay Distributions

# Multiple classes of service: scenario

# Scenario 1: mixed FTP and audio

- Example: 1Mbps IP phone, FTP or NFS share 1.5 Mbps link.
  - bursts of FTP or NFS can congest router, cause audio loss
  - want to give priority to audio over FTP

## Principle 1

packet marking needed for router to distinguish between different classes; and new router policy to treat packets accordingly

# Principles for QOS Guarantees (more)

- ❑ what if applications misbehave (audio sends higher than declared rate)
  - policing: force source adherence to bandwidth allocations
- ❑ marking and policing at network edge:
  - similar to ATM UNI (User Network Interface)

## Principle 2

provide protection (*isolation*) for one class from others

# Principles for QOS Guarantees (more)

- ❑ Allocating *fixed* (non-sharable) bandwidth to flow: *inefficient* use of bandwidth if flows doesn't use its allocation

## Principle 3

While providing **isolation**, it is desirable to use resources as efficiently as possible

# Scheduling And Policing Mechanisms

- ❑ **scheduling**: choose next packet to send on link
- ❑ **FIFO (first in first out) scheduling**: send in order of arrival to queue
  - ⇒ real-world example?
  - **discard policy**: if packet arrives to full queue: who to discard?
    - Tail drop: drop arriving packet
    - priority: drop/remove on priority basis
    - random: drop/remove randomly

# Scheduling Policies: more

**Priority scheduling:** transmit highest priority queued packet

- multiple *classes*, with different priorities
  - class may depend on marking or other header info, e.g. IP source/dest, port numbers, etc..

# Scheduling Policies: still more

## round robin scheduling:

- ❑ multiple classes
- ❑ cyclically scan class queues, serving one from each class (if available)

# Scheduling Policies: still more

## Weighted Fair Queuing:

- ❑ generalized Round Robin
- ❑ each class gets weighted amount of service in each cycle
- ❑ when all classes have queued packets, class  $i$  will receive a bandwidth ratio of  $w_i / \sum w_j$

# Policing Mechanisms

Goal: limit traffic to not exceed declared parameters

Three common-used criteria:

- ❑ *(Long term) Average Rate:* how many packets can be sent per unit time (in the long run)
  - crucial question: what is the interval length:  
100 packets per sec  
or 6000 packets per min have same average!
- ❑ *Peak Rate:* e.g., 6000 packets per min. (ppm) avg.;  
1500 pps peak rate
- ❑ *(Max.) Burst Size:* max. number of packets sent consecutively

# Policing Mechanisms

Token Bucket: limit input to specified Burst Size and Average Rate.

- ❑ bucket can hold  $b$  tokens  $\Rightarrow$  limits maximum burst size
- ❑ tokens generated at rate  $r$  token/sec unless bucket full
- ❑ *over interval of length  $t$ : number of packets admitted less than or equal to  $(r t + b)$ .*

# Policing Mechanisms (more)

- token bucket, WFQ combined provide guaranteed upper bound on delay, i.e., *QoS guarantee*

# IETF Differentiated Services

- ❑ want “qualitative” service classes
  - “behaves like a wire”
  - relative service distinction: Platinum, Gold, Silver
- ❑ *scalability*: simple functions in network core, relatively complex functions at edge routers (or hosts)
  - in contrast to IETF Integrated Services: signaling, maintaining per-flow router state difficult with large number of flows
- ❑ don't define service classes, provide functional components to build service classes

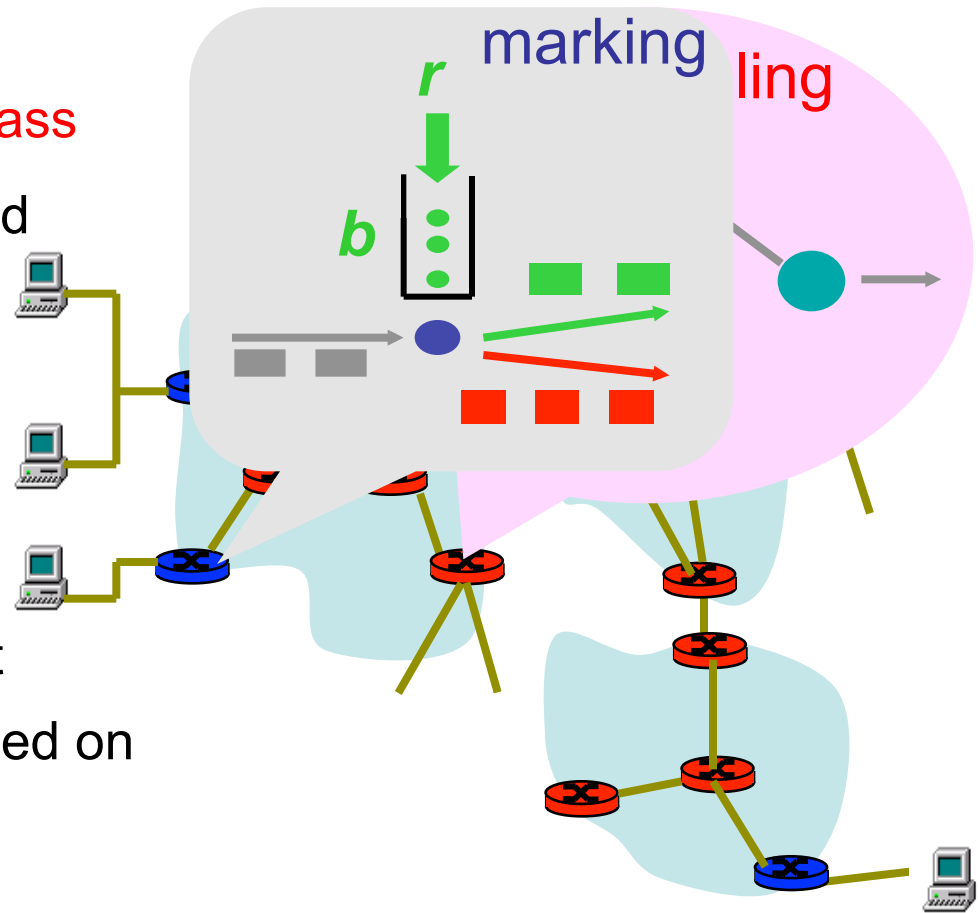

# Diffserv Architecture

## Edge router:

- per-flow traffic management
- marks packets according to **class**
- marks packets as **in-profile** and **out-profile**

## Core router:

- **per class** traffic management
- buffering and scheduling based on **marking** at edge
- preference given to **in-profile** packets

# Edge-router Packet Marking

- **profile**: pre-negotiated rate A, bucket size B
- packet marking at edge based on **per-flow** profile

## Possible usage of marking:

- class-based marking: packets of different classes marked differently
- intra-class marking: conforming portion of flow marked differently than non-conforming one

## Classification and Conditioning

- ❑ Packet is marked in the Type of Service (TOS) in IPv4, and Traffic Class in IPv6
- ❑ 6 bits used for Differentiated Service Code Point (DSCP) and determine PHB that the packet will receive
- ❑ 2 bits can be used for congestion notification: Explicit Congestion Notification (ECN), RFC 3168

# Classification and Conditioning

May be desirable to limit traffic injection rate of some class:

- ❑ user declares traffic profile (e.g., rate, burst size)
- ❑ traffic metered, shaped or dropped if non-conforming

## Forwarding (PHB)

- ❑ PHB result in a different observable (measurable) forwarding performance behavior
- ❑ PHB does not specify what mechanisms to use to ensure required PHB performance behavior
- ❑ Examples:
  - Class A gets  $x\%$  of outgoing link bandwidth over time intervals of a specified length
  - Class A packets leave first before packets from class B

## Forwarding (PHB)

PHBs being developed:

- **Expedited Forwarding:** packet departure rate of a class equals or exceeds specified rate
  - logical link with a minimum guaranteed rate
- **Assured Forwarding:** e.g. 4 classes of traffic
  - each class guaranteed minimum amount of bandwidth and a minimum of buffering
  - packets each class have one of three possible drop preferences; in case of congestion routers discard packets based on drop preference values

## Chapter outline – Quality-of-Service Support

- Providing multiple classes of service
- Providing QoS guarantees
- **Signalling for QoS**

## Principles for QOS Guarantees (more)

- *Basic fact of life:* can not support traffic demands beyond link capacity

### Principle

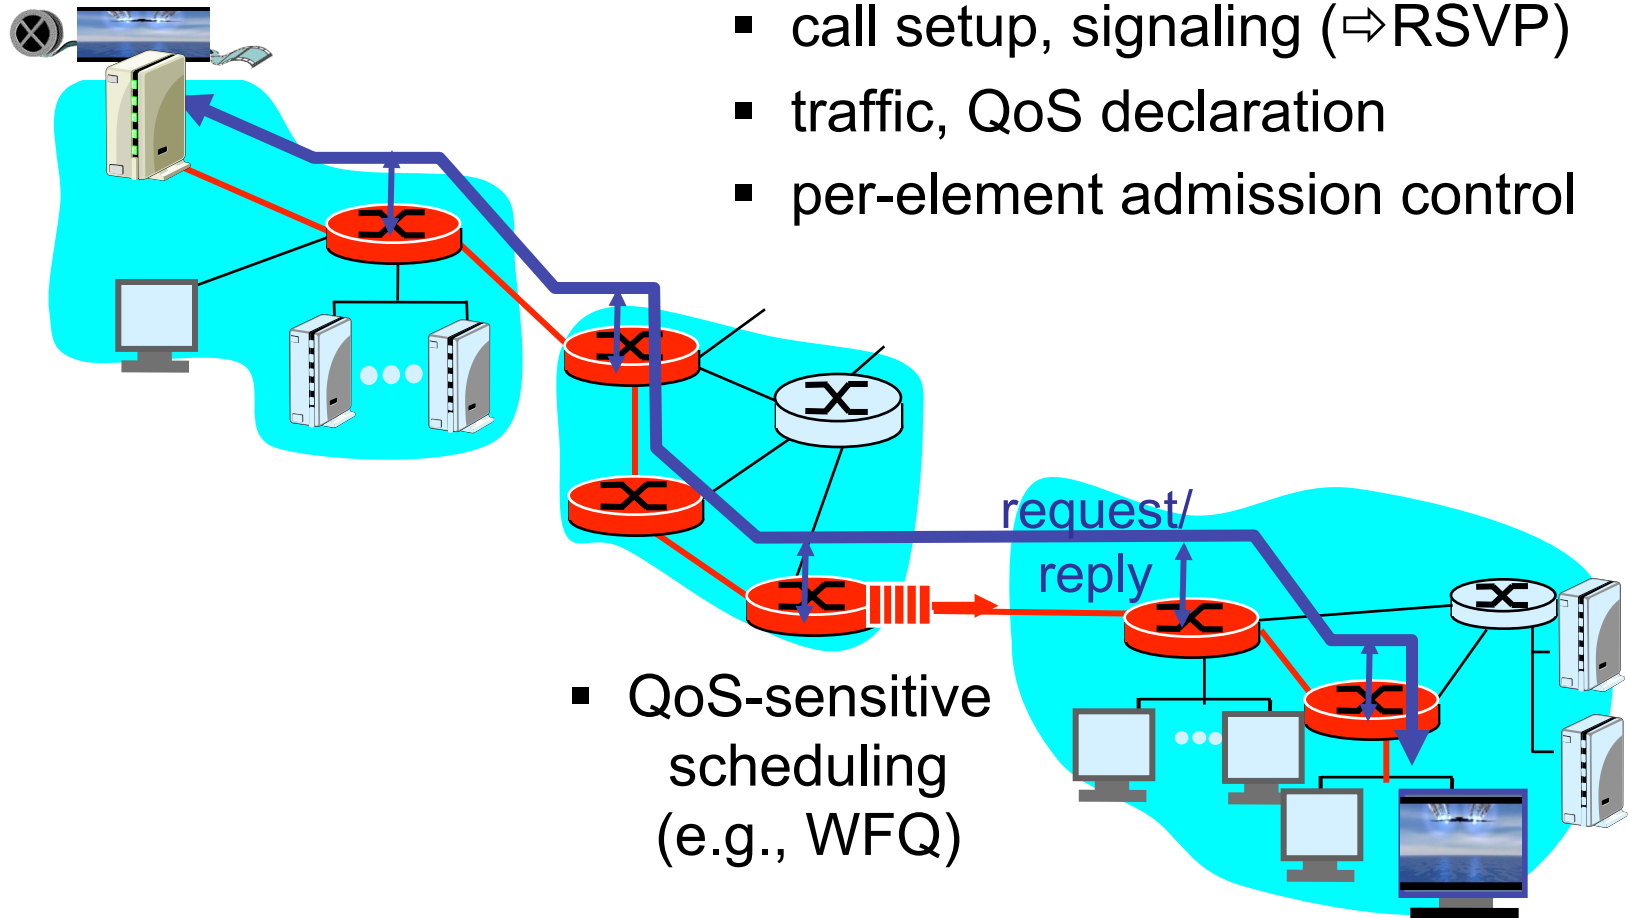

Call Admission: flow declares its needs, network may block call (e.g., busy signal) if it cannot meet needs

## □ Resource reservation

- call setup, signaling ( $\Rightarrow$ RSVP)
- traffic, QoS declaration
- per-element admission control

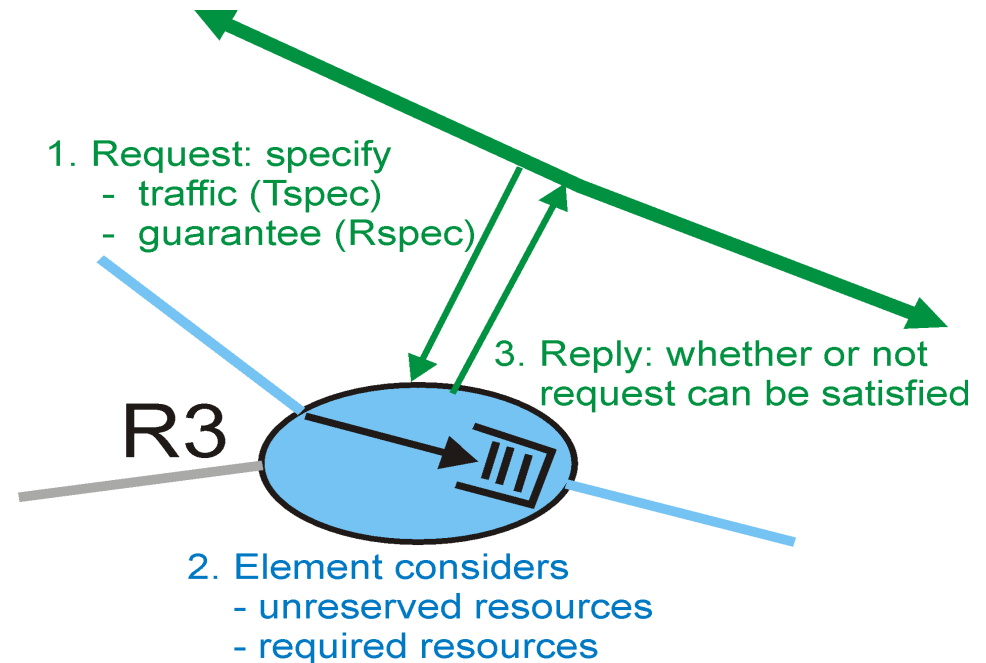

- QoS-sensitive scheduling (e.g., WFQ)

# Call Admission

- ❑ Routers will admit calls based on:
- ❑ Flow behavior:
  - R-spec and T-spec
- ❑ the current resource allocated at the router to other calls.

# IETF Integrated Services

- ❑ architecture for providing QoS guarantees in IP networks for individual application sessions
- ❑ resource reservation: routers maintain state info (as for VCs) of allocated resources, QoS requests
- ❑ admit/deny new call setup requests:

Question: can newly arriving flow be admitted with performance guarantees while not violated QoS guarantees made to already admitted flows?

# Call Admission

Arriving session must :

- declare its QoS requirement
  - **R-spec**: defines the QoS being requested
- characterize traffic it will send into network
  - **T-spec**: defines traffic characteristics
- signaling protocol: needed to carry R-spec and T-spec to routers (where reservation is required)
  - **RSVP**

# Intserv QoS: Service models [RFC 2211, RFC 2212]

## Guaranteed service:

- worst case traffic arrival: leaky-bucket-policed source
- simple (mathematically provable) *bound* on delay [Parekh 1992, Cruz 1988]

## Controlled load service:

- "a quality of service closely approximating the QoS that same flow would receive from an unloaded network element."
